ABSTRACT

Wheat belong to the genus Triticum, as annual plants of the family Gramineae or Poaceae, grown in many countries, including Tunisia with one million hectares annually. Wheat grain is a particular fruit, caryopsis and the outer envelope is adherent to plant seed material. During milling, envelopes (hulls) are separated from the grain (endosperm + embryo). The embryo or germ is the essential part of the seed to plant reproduction and is containing a lot of fat (about 15%) or oils. The Soxhlet technique is used for the extraction of wheat germ oil. Normal hexane (n-hexane) is commonly used for edible oil extraction. Comparison of the extracted oil of durum wheat germ and soft wheat germ showed a marked difference in their chemical composition. The basic chemical composition analyses revealed low values of dry matter (14.77g /100g of durum wheat germ and 19.87g /100g of Soft wheat germ), low amounts of total ash content (5.3g/100g of durum wheat germ and 4.99g /100g of Soft wheat germ) and high fat contents (17.12g /100g of durum wheat germ and 15.96g /100g of Soft wheat germ). The yield of extraction by Soxhlet was about 13.12% for durum wheat germ and 11.22% for soft wheat germ. The fatty acid composition of these two wheat germ oils indicates the presence of C18:2, C16:0 and C18:1. The major one is C18:2 with 56.68% for Soft wheat germ oil and 53.43% for durum wheat germ oil.

Keywords: germ oil, durum & soft wheats, soxhlet extraction, fatty acid composition, chemical composition

Introduction

Cereals have an important role in human nutrition, either for cooking or as raw material for obtaining flour for baking. Botanically they belong to the grass family (Gramineae), that include wheat, rice, barley, oats, rye, maize, sorghum, and millets (Belderok, 2000). Wheat is one of the most important crops in the world with the largest production of any crop. This is because it is highly adaptive to environmental conditions and because of its unique characteristics where it can be processed into various types of edible products (Shewry and Tatham, 1997). The different attributes of Triticum durum and Triticum aestivum are due to the differences in kernel physiochemical properties. Durum wheat grains are harder, larger and more vitreous than bread wheat grains. Durum wheat is tetraploid (AABB), While bread wheat is hexaploid (AABBDD), and consequently, the absence of D genome is to some extent- responsible for the
Wheat germ oil extraction was carried out according to the AOCS Official methods using n-hexane (AOCS, 1998). Oil content of wheat germ samples was determined by using a Soxhlet apparatus with n-hexane as a solvent for 6 h. Solvent used for oil extraction is n-hexane, with a highest available purity. The n-hexane solvent was done from SIGMA-ALDRICH Company (USA). All other chemicals used in this study were of analytical grade.

The extraction procedure was repeated twice and the solvent was evaporated from the extract solvent mixtures at 40°C under vacuum using a rotavapor (Rotavapor R-210/215, 230V, 50/60 Hz) until constant weight was attained. The wheat germ oils obtained was drained under a nitrogen stream (N2) and was then stored in a freezer at (-18°C) until analysis. The amount of oil extracted by solvent was gravimetrically determined. Extraction yield (Y) was defined by the following equation:

\[
Y (\%) = \frac{\text{amount of extract collected (g)}}{\text{amount of sample used for extraction (g)}} \times 100
\]

Analytical methods

Fatty acid composition

Fatty acid composition of the extracted oil was analyzed by gas chromatography (GC-SM) (Agilent 19091S-433). The GC unit was a HP-5MS equipped with a flame ionization detector (FID) and a polar phénylméthyl-siloxane capillary column (60m×25mm×0.25µm film thickness), was used for fatty acid analysis. Methylation of the fatty acids was carried out according to the AOCS Official Method Ce 2-66 (AOCS, 1998). The helium carrier gas flow rate was 1ml/min. The injector temperature was maintained at 230°C. A temperature program with total run time of 82 min was used. The column temperature, after an initial isothermal period of 2 min at 50°C, was increased to 220°C at a rate of 4°C/min, and maintained at this temperature for 37.5 min. The detector conditions were as follows: temperature 250°C, N2 flow 40 ml/min, air flow 450 ml/min and make-up gas (He) 45 ml/min. Germ
oil samples (1 ml) were injected by an auto sampler (HP-5MS, HP Company, Wilmington, DE). Peak areas were calculated and data collection was managed using an HP Chemstation.

**Organic matter and ash contents quantification**

Wheat germ samples (2.5g) induplicate for each sample were analyzed for residual water content and ash content using previously validated method (De Vasconcelos et al, 2009). Wheat germ samples were submitted to a drying processing in an oven at 105°C for 12 h, and then the samples were weighed. Dried samples are incinerated at 550°C for 3 h, and the ash content was obtained.

**Chemical analysis**

Official methods of American oil chemist’s society (AOCS, 1998) were used for the determination of the refractive index, density, acid value and iodine value of the wheat germ oils. The antioxidant activity of the wheat germ oils was determined by a β-carotene/linoleic acid system, as described by Matthus (2002).

**Results and discussion**

**Chemical composition of wheat germs**

Modern technologies of grain into flour can get the germ of up to 10-35% cuts that affect the composition and biological value of the finished product (Butkovsky et al, 2006). The extraction rate of oil through soxhlet was found 13.12% for durum wheat germ and 11.22% for bread wheat germ, which was in close agreement with the results found in the study of Dunford and Zhang (2003). Variation in oil yield could be attributed to differences in plant variety, cultivation climate, ripening stage and the extraction method used (Nyam et al, 2009). As illustrated in Table 1, the nutritional and biological value of durum and bread wheat germ were studied and found that the total ash, moisture, fat and protein levels were 4.99%, 19.87%, 15.96 % and 23.3% for bread wheat while they were 5.3%, 14.77%, 17.12% and 25.3% for durum wheat, respectively. Thus the difference in chemical composition of the two wheat germs depends significantly on the genetic characteristics of raw materials, climate, cultivation of grain, as well as its productivity. Such a chemical composition reveals the valuable potencies of such a wheat germ.

**Chemical analysis of wheat germ oils**

The results of physico-chemical parameters in Table 2 indicate that the characteristics of extracted wheat germ oils are in agreement with recent published values for these indices. The density or specific gravity of oil at any given temperature compared to water at a specified temperature is known to increase as the degree of unsaturation increases (i.e. with higher iodine value) (Muhammad, 2008). The densities values (g/ml) found for extracted durum wheat germ oil and bread wheat germ are 0.92 and 0.86. However, the iodine value for durum wheat germ oil was found to be 192.6 and 191.4 for bread wheat germ, which is also within the limits of literature (O’Brien, 2004 and Przybylski, 2004). It can be seen also that the acid values were 91.5 (g/100g) for bread wheat germ oil and 89.5(g/100g) for durum wheat germ oil. The antioxidant activity of wheat germ oils was measured by the bleaching of β-carotene. The comparison of durum wheat germ oil and bread wheat germ oil showed an appreciable antioxidant activity. In addition, studying the data in table 2 shows that beta-carotene content from durum wheat germ oil (17.12 mg/g) is greater than bread wheat germ oil (15.96 mg/g). It is indicated by the results of this work that wheat germ oils were established, could serve as a source of natural antioxidants or nutraceuticals.

**Fatty acid composition**

Fatty acids contents of wheat germ oils were obtained by GC analyses. Table 3 shows the fatty acids composition, expressed as percentage of total fatty acids, of oil samples obtained by using organic solvents and Soxhlet extraction. Total unsaturated and polyunsaturated fatty acid content of bread wheat germ oil was about 81.64 and 18.51%, respectively. While for durum wheat germ oil it was about 82.08% and 17.91% of total unsaturated and polyunsaturated fatty acid content. The most abundant saturated fatty acid was palmitic acid with more than 94% of the saturated fatty acids for bread wheat germ oil and 94.6% for durum wheat germ oil. These results are in a good agreement with the previous results reported by Lances et al, 1994, Michael et al 2006, Michael and Nurhan 2007 and Yuldasheva et al. 2010. Wheat germ n-hexane extracts consisted of about 69% linoleic acid (18:2 n6) for bread wheat germ oil and 53.9% for durum wheat germ oil, which is an essential fatty acid. It is worth mentioning that the high amount of linoleic acid makes wheat germ oil specifically prone to oxidation and degradation under the conditions used for conventional edible oil extraction and refining methods (Krings et al, 2000). It has been also suggested that unsaturated fatty acid, especially polyunsaturated fatty acid intake reduces cardiovascular heart disease (CHD) (Simopoulos, 1999). Also this fatty acid may have favorable nutritional implications and beneficial physiological effects in the prevention of cancer (Oomah et al, 2000).
Yield and quality improvement of wheat germ oils needs other process as cold pressing and supercritical CO₂ extraction. The Tunisian wheat germ is not used for human feeds, which allows us to think about industrial applications. The quantity of triturated wheat in Tunisia is about 9000 tons per day resulting in 6 tons of wheat germ, and the amount of oil that can be obtained is approximately 650 liters per day. Thus, the present study can serve as an opportunity for the industrial to invest in this field.
